INDEPENDENT PROJECT

Aegis

AI engineering workspace

Sachin Bose Pulikkathara | Data & Cloud Architecture

The problem

Engineering work is spread across issue trackers, repositories, testing tools, and AI assistants. Aegis brings these steps into a single workspace with review points for people.

My project

Aegis connects issue-tracker context with an agent workflow that plans, implements, tests, and reviews a proposed change in an isolated Git worktree. Its documented workflow keeps human approval before a change reaches the working branch.

Architecture

React frontend + Python/FastAPI backend + PostgreSQL/pgvector. A local companion connects repository tooling and coding CLIs. The design supports cloud model providers and local models through Ollama.

Engineering focus

Workflow orchestration; repository and tracker integration; test and review gates; local/cloud model flexibility; traceable proposed changes.

Status

Independent implementation and public demonstration. This brief describes documented capabilities; it does not claim customer adoption, measured productivity gains, or independently validated security.
