IMPLEMENTATION CASE STUDY

SchoolHub

Multi-tenant education platform

Sachin Bose Pulikkathara | Data & Cloud Architecture

The problem

Institutions need connected staff, student, academic, and public website workflows, with institution-specific data and appropriate access for different roles.

My project

SchoolHub combines a staff CRM, a Python API, relational storage, and a separate white-label website renderer. Documented modules cover staff, students, parents, attendance, examinations, grades, fees, leave, and website content.

Architecture

React / TypeScript CRM + FastAPI / SQLAlchemy backend + PostgreSQL. A separate public renderer reads institution website configuration. Docker Compose supports local development.

Key design decisions

Keep internal CRM workflows separate from public website delivery. Use tenant and role context in the backend. Reuse shared application capabilities while validating institution boundaries and published-content access.

Illustrative scenario

A fictional Example Academy records attendance in its staff CRM while visitors read published admissions content through the public renderer. This example uses no real student or institution data.

Status and evidence

Repository implementation and local development documentation; source remains private.
Production-readiness work includes tenant-isolation tests, authorization review, removal of development authentication shortcuts, backup/restore checks, and monitoring.
